

Thermoelectric effects and their applications in thermoelectric generator and refrigerator (10 pt)

Introduction: Thermoelectric effects

Thermoelectric effects in conducting materials are due to the interplay between heat current and electrical current. In this problem we consider only three predominant thermoelectric effects, namely the Joule, the Seebeck and the Peltier effects, neglecting the others.

The Joule effect is a consequence of the interaction between electrical carriers and crystal lattice. Moving directionally in presence of electrical current, carriers transfer a part of their energy to the vibrating crystal lattice, and as a result the crystal is heated. The Joule effect is irreversible.

The Seebeck effect can be observed in a thermocouple consisting of two dissimilar conducting bars A and B connecting by direct junction (Fig. 1a) or junction via an intermediate material C (Fig. 1b). The material C is good electrical conductor with very small specific heat. When the two junctions of the thermocouple are maintained at different temperatures T_1 and T_2 (Fig. 1a,b) the Seebeck electromotive force (*emf*) is produced

$$\epsilon = \alpha(T_1 - T_2) \quad (1)$$

where α is the Seebeck coefficient of the thermocouple. α is considered temperature independent. The Seebeck effect is applied in thermoelectric generator to convert heat energy into electrical one.

Figure 1. (a) direct junctions. (b) junctions via an intermediate material C. (1) Heat source (temperature T_1); (2) Heat sink (temperature T_2)

The Peltier effect

Whenever current passes through a thermocouple circuit consisted of two dissimilar conductors A and B with direct junctions (Fig. 2a) or junctioned via intermediate conductor C (Fig. 2b), depending on the

current direction, either heat is absorbed or released at the junctions of the two conductors. This is the Peltier effect. The Peltier heat power q appeared at a junction is

$$q = \pi I \quad (2)$$

π is the Peltier coefficient of this junction. The Seebeck and Peltier effects are reversible effects in contrast to the irreversible Joule effect. Although the Seebeck and Peltier effects need junctions between the thermoelements, they are essentially bulk effects. A closed electrical cycle in a thermocouple with the Peltier effect (Fig. 2b) can be used as a refrigerator when heat is removed from one isolated junction and rejected at the other.

For simplicity, the heat radiation, circulation, conduction through surrounding environment are considered negligible, and heat current is supposed to be inside the thermocouple and at the heat source and the heat sink.

Figure 2. (a) Direct junctions; (b) junctions via an intermediate material C

Data for thermal and electrical properties of materials and the thermocouple studied in this problem are given in the Table 1 and 2 for numerical calculation.

Name	Material	Resistivity ρ ($\Omega \cdot \text{m}$)	Thermal conductivity k ($\text{W} \cdot \text{m}^{-1} \cdot \text{K}^{-1}$)
A	$\text{Bi}_2\text{Te}_{2.7}\text{Se}_{0.3}$	1.0×10^{-5}	1.4
B	$\text{Bi}_{0.5}\text{Sb}_{1.5}\text{Te}_3$	1.0×10^{-5}	1.4

Table 1: Parameters of materials used in thermocouple (at room temperature)

Thermocouple AB	Length (m)	Seebeck's coefficient α ($\mu\text{V} \cdot \text{K}^{-1}$)
	0.02	420

Table 2: Parameters of the thermocouple.

A. Heat transfer and thermoelectric generator

A1. Heat transfer in a homogeneous conducting bar

An electric current I (Figure 3) flows along a homogeneous conducting bar with length L , resistivity ρ , thermal conductivity k . The two ends of the bar are located at coordinates $x = 0$ and $x = L$ in the Ox axis. The temperature at $x = 0$ is T_1 , at $x = L$ is T_2 ($T_1 > T_2$), both temperatures are kept constant.

Figure 3

The heat current $q(x)$ (the amount of heat transferred via perpendicular cross-section per unit time) flowing in the bar is described by the Fourier law

$$q(x) = -kS \frac{dT(x)}{dx} \quad (3)$$

here k is thermal conductivity, and S is the cross-sectional area of the bar.

A1.1 Find the temperature distribution $T(x)$ when x varies along the bar at the steady state assuming no heat loss to the surroundings. 0.75pt
Hint: the equation $\frac{d^2T(x)}{dx^2} = a$ has the solution $T(x) = \frac{1}{2}ax^2 + C_1x + C_2$, where C_1 and C_2 are derived from boundary conditions.

A1.2 Find the heat current $q(x)$ at point x and $q(0)$, $q(L)$ at the two ends, respectively. 1.0pt

A2. Relation between Peltier and Seebeck Coefficients

Relation between Peltier and Seebeck coefficients for all temperature range is generally proved in thermodynamics. Here, this relation is derived for the particular case when the thermocouple is made of conducting materials A and B (Fig.1b) with the Seebeck coefficient α and small-enough resistivity so that the Joule effect can be neglected. The Peltier coefficients at the hot (temperature T_1) and cold (temperature T_2) junctions are π_1 and π_2 correspondingly. During electrical process, the electron gas in the thermocouple performs an ideal thermodynamic cycle.

A2.1 Find the expression for the heat current received by the electron gas from the heat source with temperature T_1 . 0.25pt

- A2.2** Find the expression for the heat current transferred by the electron gas to the heat sink with temperature T_2 . 0.25pt
- A2.3** Find the net electrical power produced by the electron gas if the Seebeck coefficient is α . 0.5pt
- A2.4** Express the Peltier coefficient at a junction in term of the Seebeck coefficient α and the temperature T of the junction. 0.5pt

A3. Thermoelectric generator

Figure 4. Thermoelectric generator. (1) Heat source (temperature T_1); (2) Heat sink (temperature T_2).

Hereafter the Peltier coefficient π is taken to be equal to αT for all temperatures and the Joule heat must be included in consideration.

The thermocouple consisting of two conducting bar A and B with equal length L is used as thermoelectric generator (Fig. 4). The parameters of the bars A and B are: cross-sectional areas S_A, S_B ; resistivities ρ_A, ρ_B ; thermal conductivities k_A, k_B . The lower ends of the A and B bars are connected to a load of resistance R_L . Parameters of the thermocouple are: α the Seebeck coefficient, $R = \frac{\rho_A L}{S_A} + \frac{\rho_B L}{S_B}$ the internal resistance, $K = \frac{k_A S_A}{L} + \frac{k_B S_B}{L}$ the thermal conductance. The upper hot end (lower cold end) of the thermocouple is maintained at temperature T_1 (T_2) and $T_1 > T_2$. Denote q_1 as the heat power taken from the heat source with temperature T_1 , q_2 the heat power transferred to the heat sink with temperature T_2 by the thermocouple.

- A3.1** Find the expressions for q_1, q_2 in terms of the thermocouple parameters $\alpha, K, R,$ the temperatures T_1, T_2 and the current I 0.5pt

The efficiency of the thermoelectric generator is defined as $\eta = \frac{P_L}{q_1}$, where P_L the electrical power of the load. The ratio between the load and internal resistances of the thermocouple is denoted as $m = \frac{R_L}{R}$

- A3.2** Find the expression for the efficiency η in terms of the thermocouple parameters $\alpha, K, R,$ the temperatures T_1, T_2 and the resistance ratio m 0.75pt

In order to get efficiency of thermoelectric generators, the following properties of the thermocouple are needed: low electrical resistance to minimize Joule heating, low thermal conductivity to retain heat at the junctions, and a maintained large temperature gradient. These three properties are put together in one quantity $Z = \frac{\alpha^2}{KR}$, which is called the figure-of-merit of the thermocouple.

- A3.3** Find the expression for the efficiency in terms of $Z,$ the ideal Carnot cycle efficiency $\eta_c = \frac{T_1 - T_2}{T_1},$ T_1 and $m.$ 0.25pt

A4. The maximum efficiency

The efficiency of the thermocouple equals η_P when the electric power of the load takes the maximum value, $P_L = P_{\max}.$

- A4.1** Find the expression for the η_P in terms of the figure of merit $Z, T_1, T_2.$ 0.25pt

The efficiency is maximum $\eta = \eta_{\max}$ when the resistance ratio m takes some value which is denoted by $M.$

- A4.2** Find the expression for M in terms of T_1, T_2 and $Z.$ 0.75pt

- A4.3** Express the maximum efficiency η_{\max} via T_1, T_2, Z and $M.$ 0.25pt

A5. The maximum figure of merit

Increasing the figure of merit of the thermocouple leads to the increase of the efficiency of the thermoelectric generator. In practice, the cross-sectional areas S_A, S_B of the bars of the thermocouple are chosen so that the figure of merit of the thermocouple has maximum value $Z = Z_m$

- A5.1** Derive the expression for the ratio between the cross-sectional areas $\frac{S_A}{S_B}$ of the bars in terms of ρ_A, ρ_B, k_A, k_B when the figure of merit of the thermocouple is maximum. 0.5pt

- A5.2** Express the maximum figure of merit Z_m in term of $\alpha, \rho_A, \rho_B, k_A, k_B$ 0.25pt

A6. The optimum efficiency

The optimum efficiency η_{opt} of the thermoelectric generator is defined as the efficiency when the electric power at the load and the figure of merit both are at the maximum values. The hot heat source and cold heat sink are maintained at temperatures $T_1 = 423$ K, $T_2 = 303$ K respectively.

A6.1 Find the numerical value η_{opt} of the thermoelectric generator made from materials with parameters given in Table 1 and compare it with the ideal efficiency η_c . 0.5pt

A6.2 Find the numerical value of the maximum efficiency η_{max} of the thermoelectric generator made from given materials. 0.25pt

B. Thermoelectric refrigerator

The thermocouple with parameters α , K , R given in the question A3 is used as a thermoelectric refrigerator and described in the Fig.5.

B1. The cooling power and the maximum temperature difference

The upper end of the thermocouple is a heat source with the initial temperature T_1 . It is thermally isolated with ambient environment, and needs to be cooled. The lower ends of the thermocouple, A and B bars are connected to a battery and are at the temperature T_2 of the heat sink. The sense of the electrical current is chosen so that the Peltier heat is absorbed at the upper junction and released to the heat sink at the lower junction.

Figure 5. Thermoelectric refrigerator. (1) Isolated heat source (temperature T_1); (2) Heat sink (temperature T_2)

B1.1 Find the expression for the cooling power q_C (heat current flows from the heat source to the bars of the thermocouples) in terms of the thermocouple parameters α , K , R and T_1 , T_2 , I . 0.25pt

B1.2 Find the expression for the maximum temperature difference $\Delta T_{\max} = T_2 - T_{1\min}$ in term of the figure of merit Z of the thermocouple and the lowest temperature of the isolated heat source $T_{1\min}$. 0.5pt

B2. The working current

The thermocouple made from materials A and B with best value of figure of merit Z_m found in part A is used for the refrigerator.

B2.1 Calculate the numerical value of the minimum temperature of the isolated heat source $T_{1\min}$ if the temperature of the heat sink is $T_2 = 300K$. 0.25pt

B2.2 Calculate the working current intensity I_w of the thermoelectric refrigerator when the temperature of the heat source is at the minimum value $T_{1\min}$ and the temperature of the heat sink $T_2 = 300K$. For simplicity the cross-sectional areas of the bars are taken to be equal, $S_A = S_B = 10^{-4}m^2$. 0.5pt

B3. The coefficient of performance

When the temperature difference is less than its maximum value ΔT_{\max} , the coefficient of performance β is usually used for assessing of the performance of the thermoelectric refrigerator. $\beta = \frac{q_C}{P}$, where P is the supplied electrical power.

B3.1 Find the expression for the coefficient of performance β in terms of the parameters α , K , R of the thermocouple and T_1 , T_2 , I . 0.5pt

When the coefficient of performance has its maximum value β_{\max} , the current intensity is I_β .

B3.2 Find the expression for I_β in terms of the parameters α , Z , R of the thermocouple and temperatures T_1 , T_2 . 0.25pt

B3.3 Find the expression for the maximum coefficient of performance β_{\max} . 0.25pt
